

# **Engineering the Storm: Principles of Hydrology & Urban Water Management**

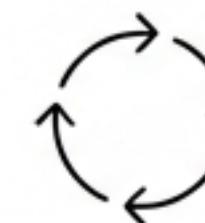

**From Watersheds to Hydrographs: Quantifying  
and Managing Runoff in the Built Environment.**

# The Fundamental Unit: The Watershed

A watershed is an area of land where all of the water that falls under it and drains off of it goes to a common outlet.

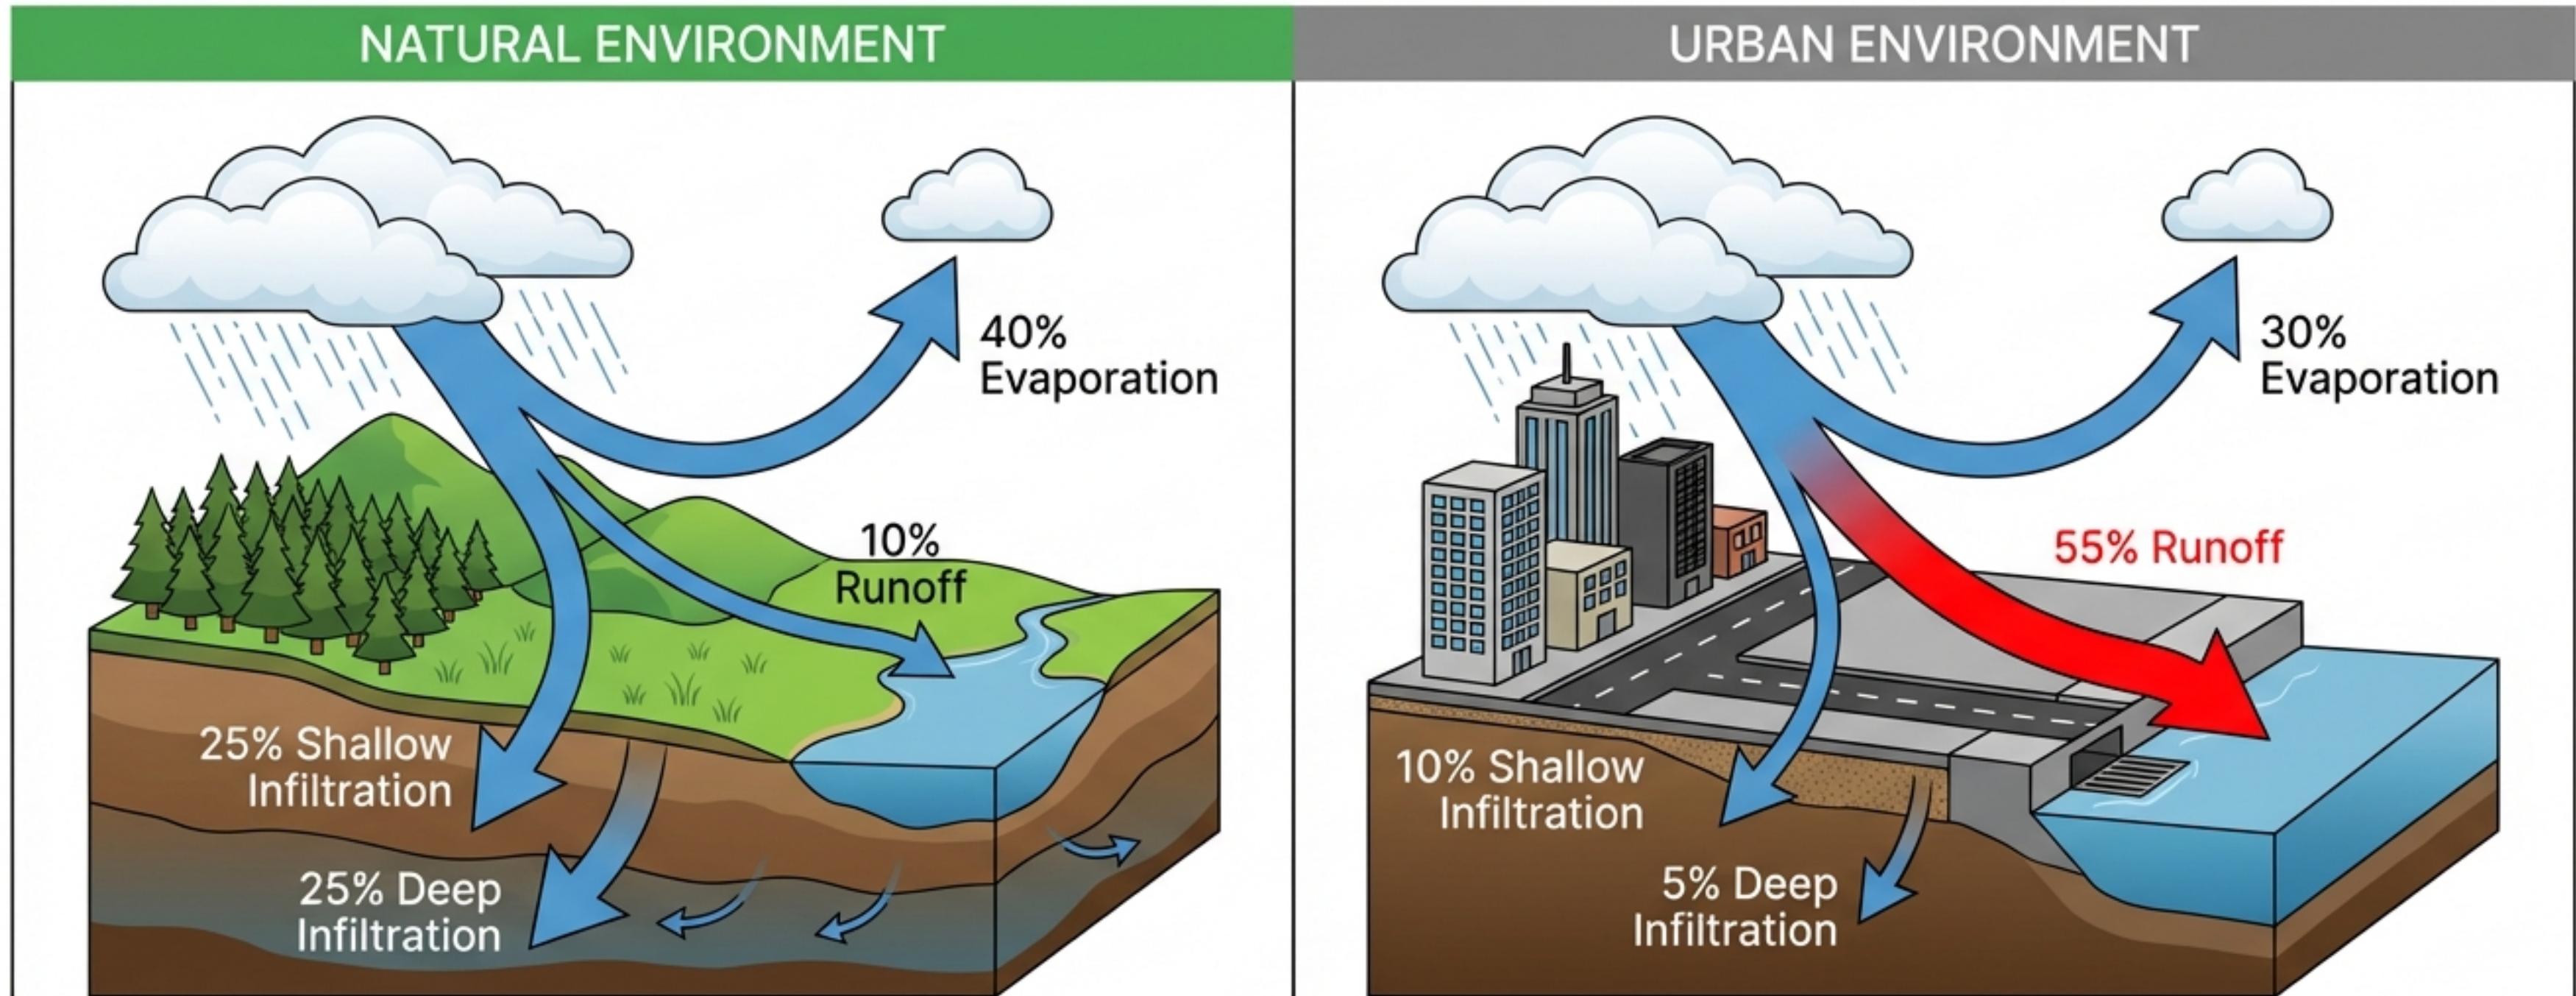

Water is in constant motion—evaporation, transpiration, precipitation, and runoff.

In a natural state, the cycle is balanced. In an engineered environment, we must calculate how much of that precipitation becomes 'Direct Runoff' versus how much is lost to infiltration and evaporation.

# The Conflict: Urbanization vs. Infiltration

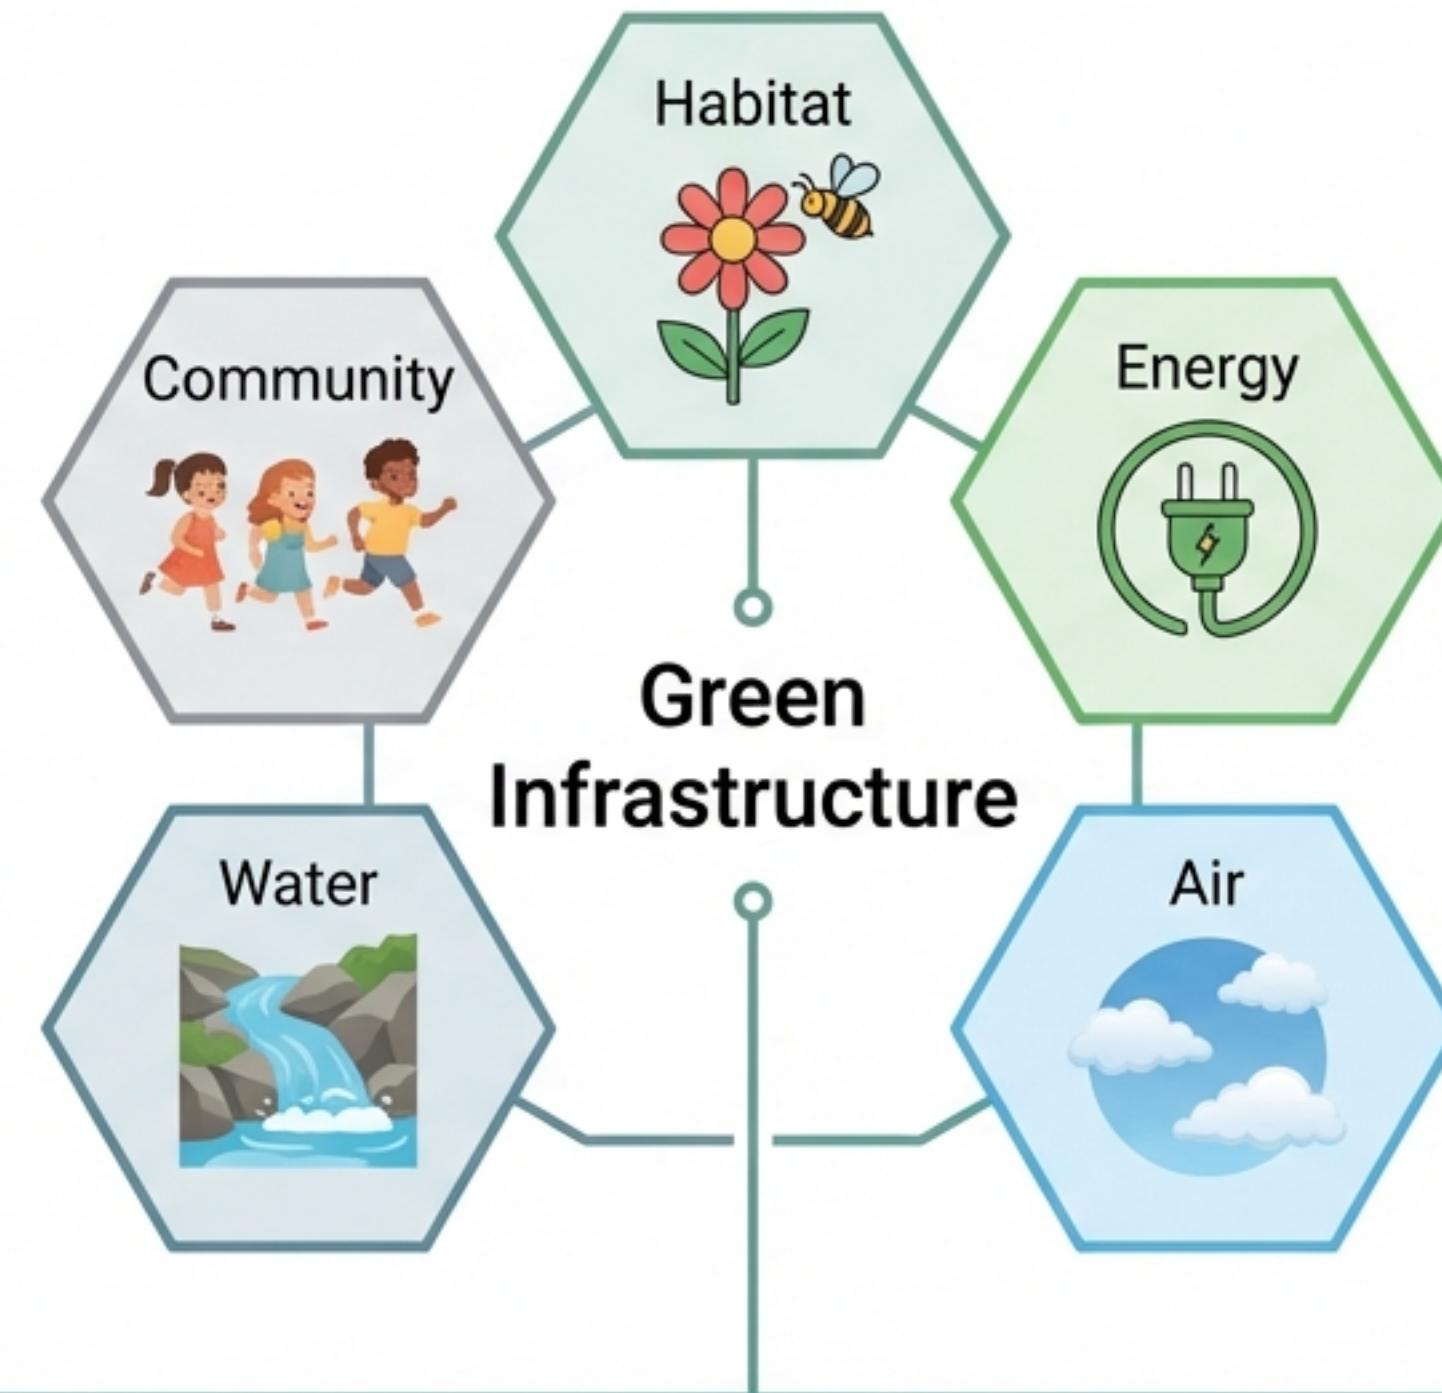

"As we replace soil with concrete, we lose the earth's natural sponge. In New York City, for example, the land is more than 66% impervious. This shift requires precise engineering to handle the excess volume."

# Gray vs. Green: A Philosophy of Management

**Gray Infrastructure**

Single-purpose. Uses pipes to dispose of rainwater quickly.

**Green Infrastructure**

Multi-functional. Uses vegetation and soil to manage rainwater where it falls.

**Core Benefit:** By weaving natural processes into the built environment, we achieve stormwater management alongside flood mitigation and air quality improvement.

# Input Data: Quantifying Rainfall

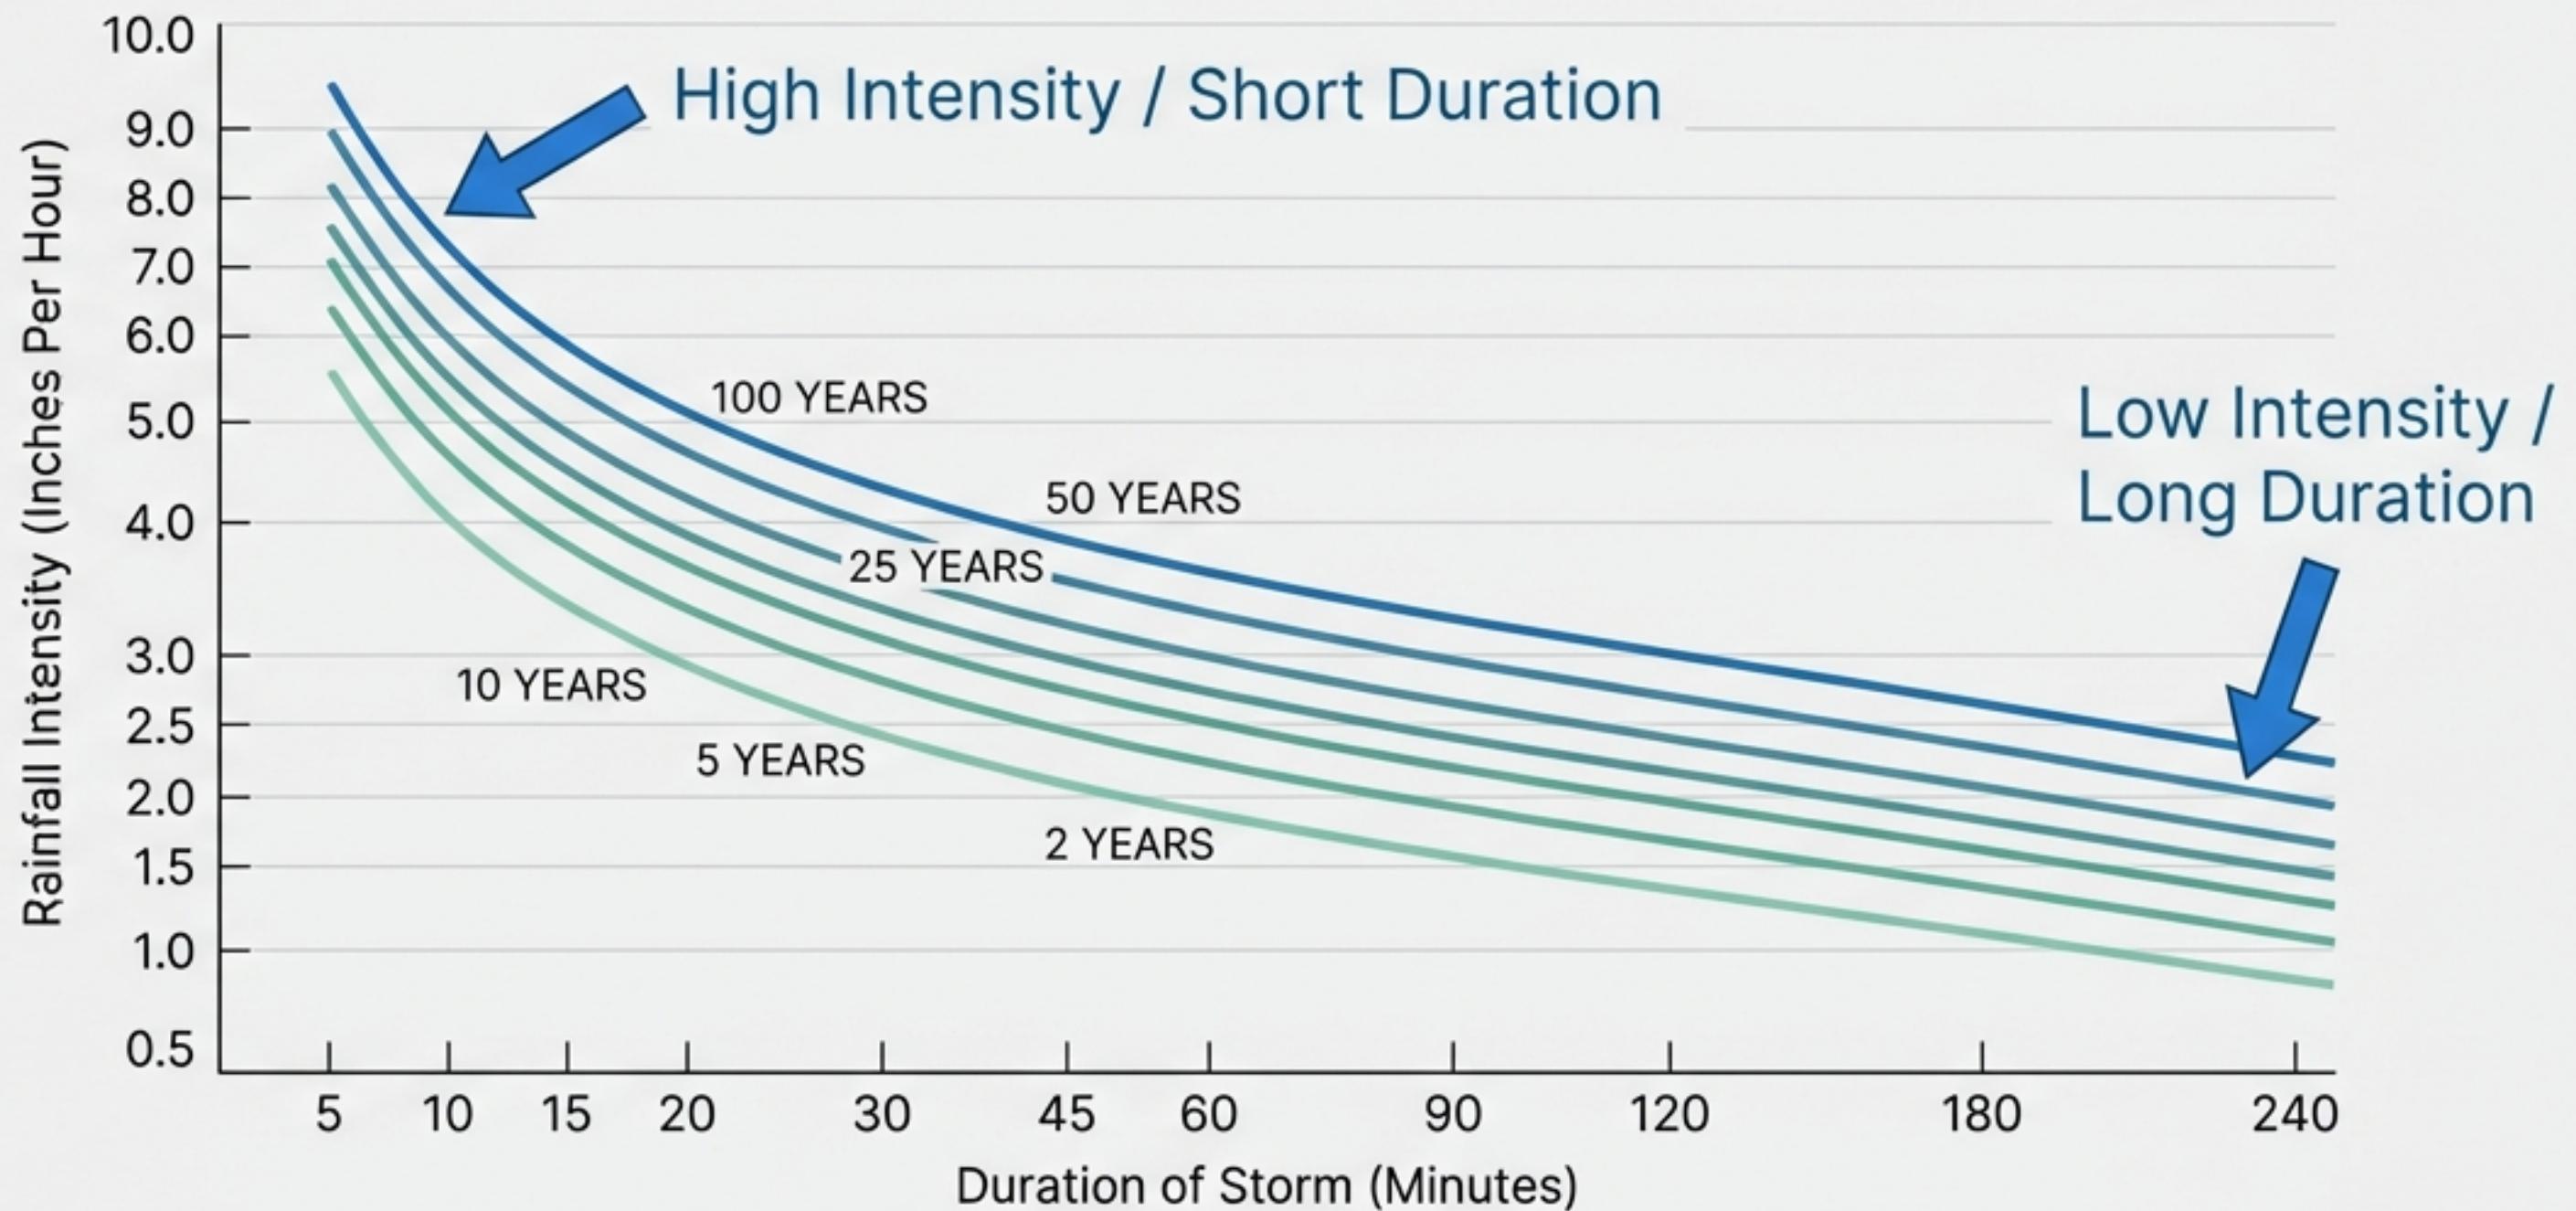

Engineers characterize storms by three metrics: Depth, Duration, and Frequency.

| Duration | Average recurrence interval (years) |                  |                  |                  |                  |                  |                  |                   |                    |                    |
|----------|-------------------------------------|------------------|------------------|------------------|------------------|------------------|------------------|-------------------|--------------------|--------------------|
|          | 1                                   | 2                | 5                | 10               | 25               | 50               | 100              | 200               | 500                | 1000               |
| 5-min    | 0.5 (0.01-0.92)                     | 4.7 (0.21-1.03)  | 3.1 (0.52-1.06)  | 5.4 (0.91-1.18)  | 7.1 (0.04-1.88)  | 9.6 (0.51-1.08)  | 11.3 (1.34-1.12) | 12.5 (0.74-1.88)  | 10.7 (0.09-1.50)   | 12.2 (0.89-1.17)   |
| 10-min   | 0.00 (0.07-1.02)                    | 0.05 (0.51-1.35) | 1.15 (0.31-1.89) | 1.20 (0.53-1.87) | 1.67 (0.36-1.83) | 1.83 (0.38-1.73) | 1.36 (1.67-2.20) | 1.89 (0.64-2.23)  | 1.88 (0.01-2.99)   | 1.95 (0.38-2.54)   |
| 15-min   | 0.81 (0.07-1.26)                    | 10.3 (0.61-1.81) | 15.5 (0.42-1.99) | 16.7 (0.36-2.11) | 1.83 (0.28-1.95) | 2.33 (0.06-2.85) | 1.95 (1.05-2.93) | 2.73 (0.01-2.93)  | 2.34 (0.88-2.58)   | 28.7 (0.97-3.57)   |
| 15-min   | 0.20 (0.07-1.34)                    | 0.30 (0.61-1.96) | 1.53 (0.85-2.02) | 2.00 (0.01-2.70) | 2.33 (0.74-2.02) | 3.90 (2.26-2.76) | 2.21 (1.83-2.76) | 2.69 (1.03-3.37)  | 3.09 (2.68-3.28)   | 3.94 (9.42-4.03)   |
| 30-min   | 0.08 (0.07-1.55)                    | 0.60 (0.39-2.03) | 0.75 (0.03-2.28) | 2.33 (0.16-2.74) | 2.98 (1.03-2.33) | 4.28 (3.83-3.33) | 3.65 (3.38-3.58) | 3.85 (3.33-3.78)  | 3.96 (1.79-3.91)   | 4.85 (1.89-5.07)   |
| 60-min   | 0.99 (0.03-1.07)                    | 0.70 (0.73-2.41) | 9.07 (0.73-2.56) | 2.56 (0.99-3.03) | 3.16 (0.61-3.54) | 5.80 (3.01-3.88) | 4.73 (2.21-4.50) | 3.35 (3.56-4.00)  | 4.91 (5.01-4.14)   | 5.53 (5.15-6.19)   |

 **The Gold Standard:**  
NOAA Atlas 14 is  
the authoritative  
source for  
precipitation  
frequency  
estimates.

**Key Concept:** A “100-year storm” doesn’t happen every 100 years; it has a 1% chance of occurring in any given year.

# The IDF Curve: Intensity-Duration-Frequency

**Key Insight:** Rainfall intensity is inversely proportional to duration. A 5-minute burst is far more intense than a 24-hour drizzle. This relationship dictates how we design pipes and basins.

# Effective Precipitation: What Actually Runs Off?

$$P_e = P - \text{Losses}$$

$P_e$  = Effective Precipitation  
(Runoff Depth)

$P$  = Total Rainfall

Interception, Depression Storage,  
Infiltration, Evaporation

## Method 1: The Rational Method

Used for peak discharge ( $Q_p$ ) in small areas.

## Method 2: The NRCS (SCS) Curve Number Method

Used for volume and flow in larger, complex watersheds.

# Method 1: The Rational Method

$$Q_p = C_i A$$

Diagram illustrating the Rational Method formula:

- Peak Discharge ( $Q_p$ ):** Represented by the letter  $Q_p$  on the left.
- Runoff Coefficient (dimensionless):** Represented by the letter  $C_i$  in the middle.
- Rainfall Intensity (in/hr):** Represented by the letter  $A$  on the right.

Annotations below the formula:

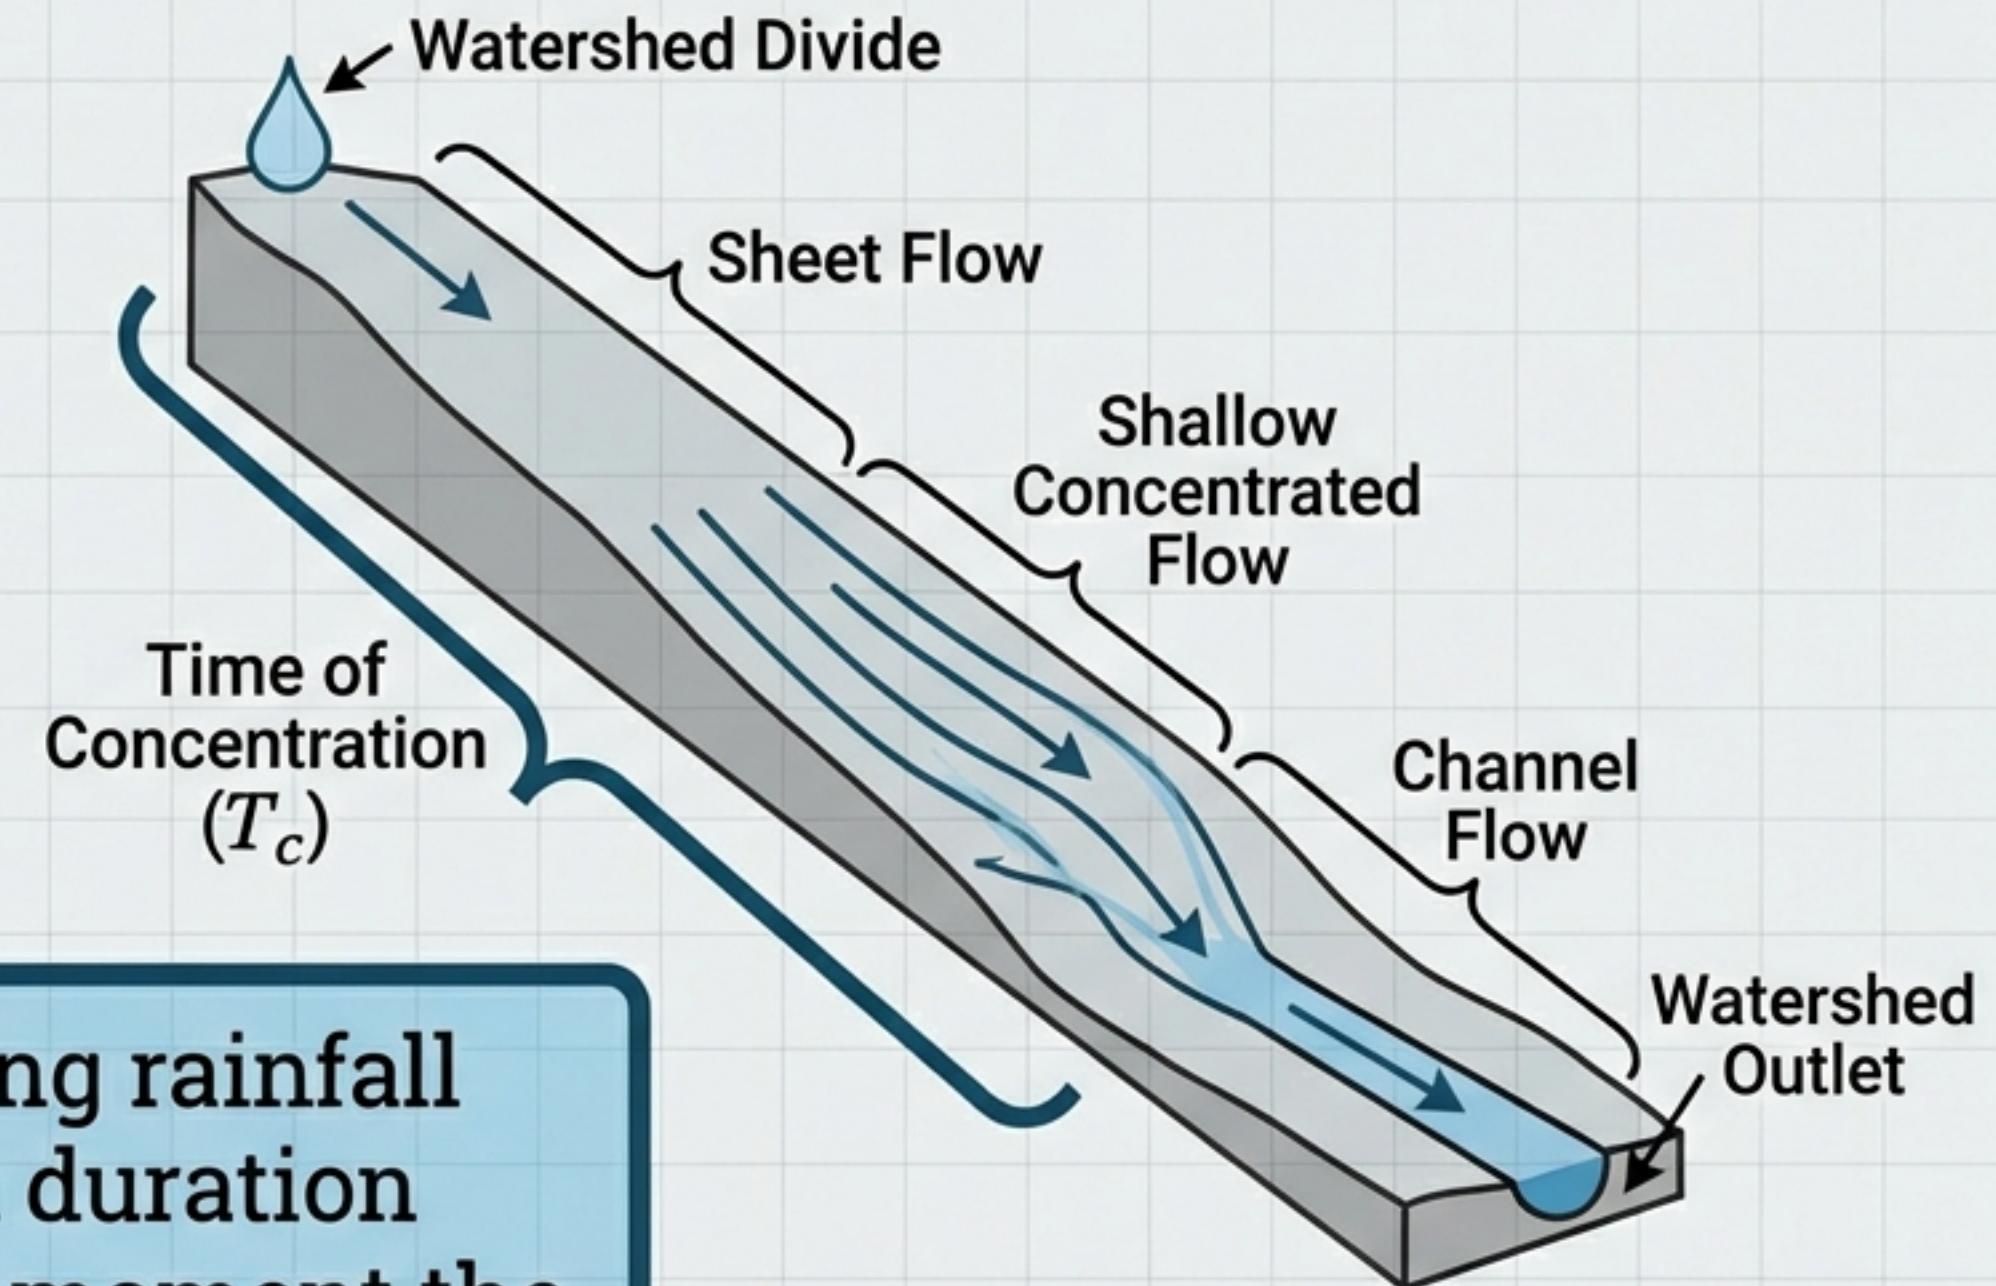

- An arrow points from the left side of  $Q_p$  to the text "Peak Discharge (cfs)".
- An arrow points from the left side of  $C_i$  to the text "Runoff Coefficient (dimensionless) (dimensionless surface impermeability)".
- An arrow points from the right side of  $A$  to the text "Drainage Area (acres)".
- An arrow points from the right side of  $A$  to the text "Rainfall Intensity (in/hr)".

## Typical Runoff Coefficients

| Description of Area                | Runoff Coefficient |
|------------------------------------|--------------------|
| Business: Downtown areas           | 0.70-0.95          |
| Business: Neighborhood areas       | 0.50-0.70          |
| Residential: Single-family areas   | 0.30-0.50          |
| Residential: Multiunits, attached  | 0.60-0.75          |
| Residential: Residential, suburban | 0.25-0.40          |
| Industrial: Light areas            | 0.50-0.80          |
| Parks, cemeteries                  | 0.10-0.25          |
| Pavement: Asphalt or concrete      | 0.70-0.95          |
| Roofs                              | 0.75-0.95          |
| Lawns, sandy soil: Flat, 2%        | 0.05-0.10          |
| Lawns, sandy soil: Average, 2%-7%  | 0.10-0.15          |
| Lawns, heavy soil: Flat, 2%        | 0.13-0.17          |
| Source: ASCE (1992).               |                    |

# Critical Parameter: Time of Concentration ( $T_c$ )

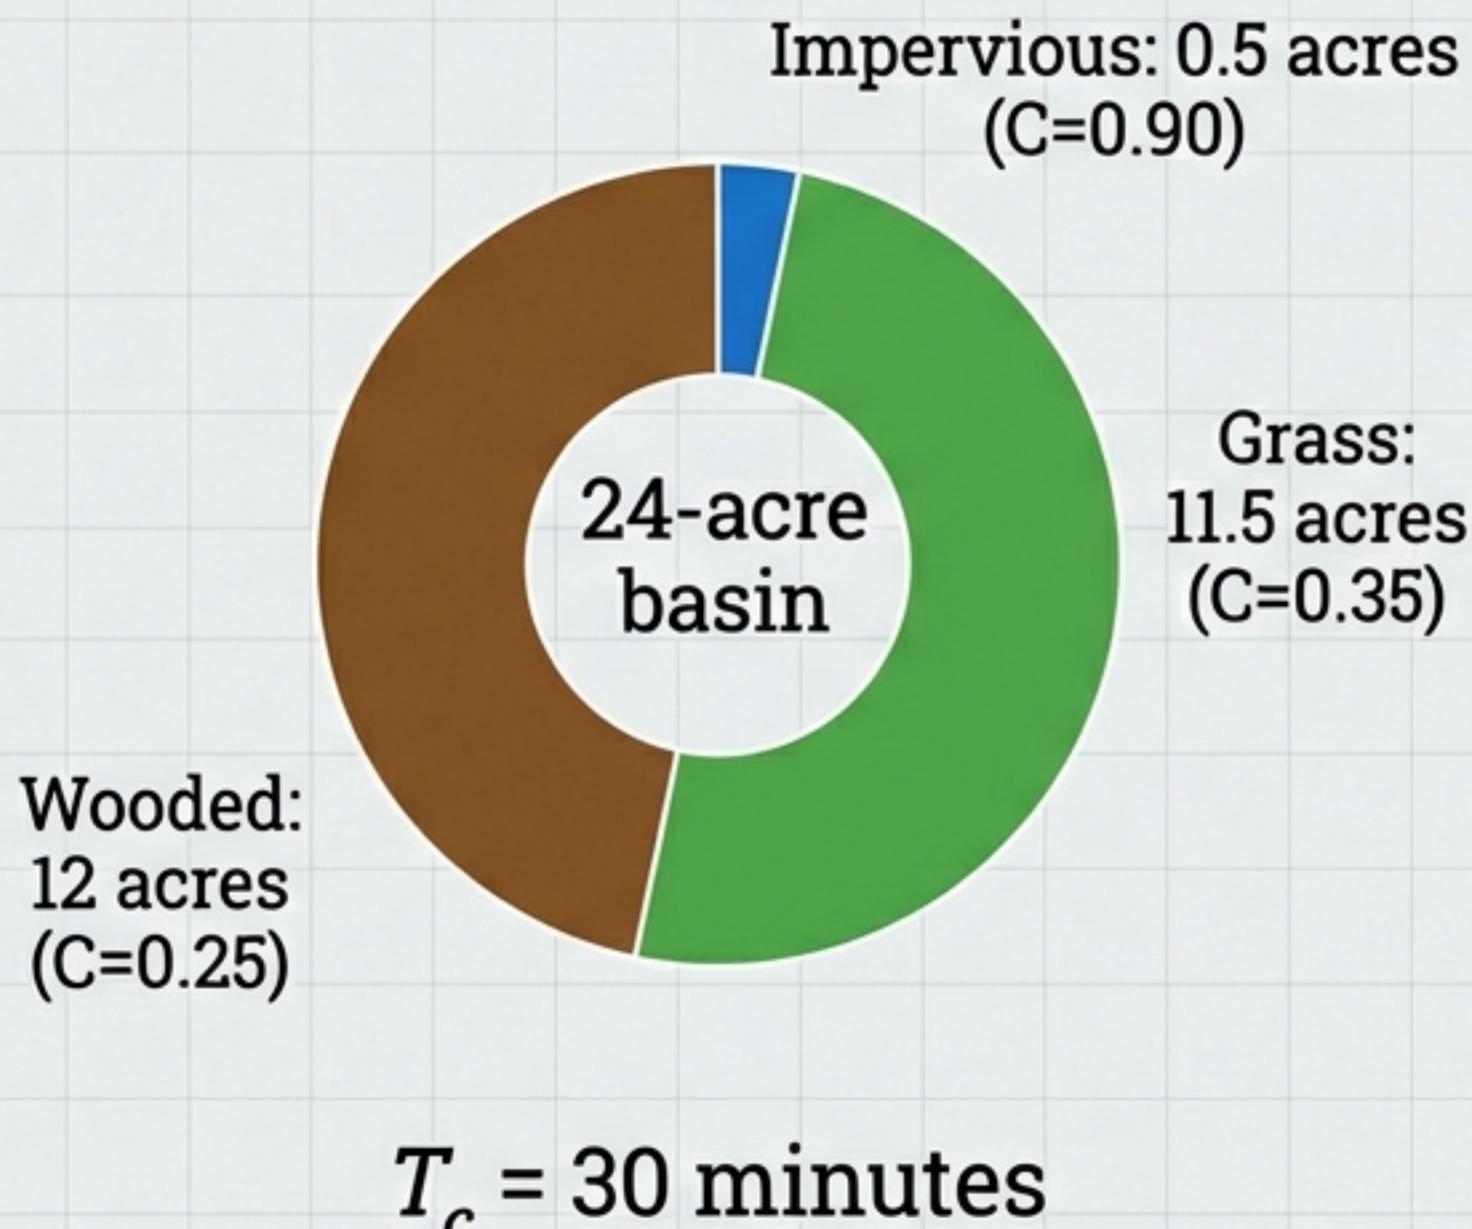

**Definition:** The longest time required for a drop of water to travel from the most remote point of the watershed divide to the watershed outlet.

**Design Rule:** When determining rainfall intensity ( $i$ ), we set the storm duration equal to  $T_c$ .  $T_c$  represents the moment the entire basin contributes to the flow.

# Case Study: Rational Method in Action

## The Scenario

## The Calculation

### Step 1. Weighted C Calculation

$$\text{Composite } C = \frac{(0.9 \times 0.5) + (0.35 \times 11.5) + (0.25 \times 12)}{24} = 0.31$$

### Step 2: Determine Intensity ( $i$ )

From IDF Curve @ 30 min duration:

$$i = 3.7 \text{ in/hr}$$

### Step 3: Calculate Peak Discharge ( $Q_p$ )

$$Q_p = 0.31 \times 3.7 \times 24 = 27.5 \text{ cfs}$$

# Method 2: The NRCS (SCS) Curve Number Method

## Calculating Volume based on Soil and Land Use

Instead of a simple "C", we use a Curve Number (CN) derived from Land Use + Hydrologic Soil Group.

- Soil Group A: High infiltration (Sand)
- Soil Group D: Low infiltration (Clay)

Potential Maximum Retention:

$$S = 1000/CN - 10$$

Effective Runoff:

$$Pe = (P - 0.2S)^2 / (P + 0.8S)$$

|   | Runoff Curve Numbers |    |    |    |  |
|---|----------------------|----|----|----|--|
|   | Soil Group           |    |    |    |  |
|   | A                    | B  | C  | D  |  |
| Open space (lawns, parks, etc.)           |                      |    |    |    |  |
| Poor condition                            | 68                   | 79 | 86 | 89 |  |
| Fair condition                            | 49                   | 69 | 79 | 84 |  |
| Good condition                            | 39                   | 61 | 74 | 80 |  |
| Residential districts by average lot size |                      |    |    |    |  |
| 1/8 acre or less                          | 77                   | 85 | 90 | 92 |  |
| 1/4 acre                                  | 61                   | 75 | 83 | 87 |  |
| 1/3 acre                                  | 57                   | 72 | 81 | 86 |  |
| 1/2 acre                                  | 54                   | 70 | 80 | 85 |  |
| 1 acre                                    | 51                   | 68 | 79 | 84 |  |
| 2 acres                                   | 46                   | 65 | 77 | 82 |  |

# Case Study: NRCS Method in Action

400-acre basin, Middlesex, NJ. Soil Group B. Rainfall (P) = 6.36 inches.

## Step 1: Calculate Weighted Curve Number

Based on mixed land use (Impervious, Wooded, Meadow, Residential), the weighted average CN is determined to be **61.7**.

## Step 2: Calculate Potential Retention (S)

$$S = \frac{1000}{61.7} - 10 = \mathbf{6.21 \text{ inches}}$$

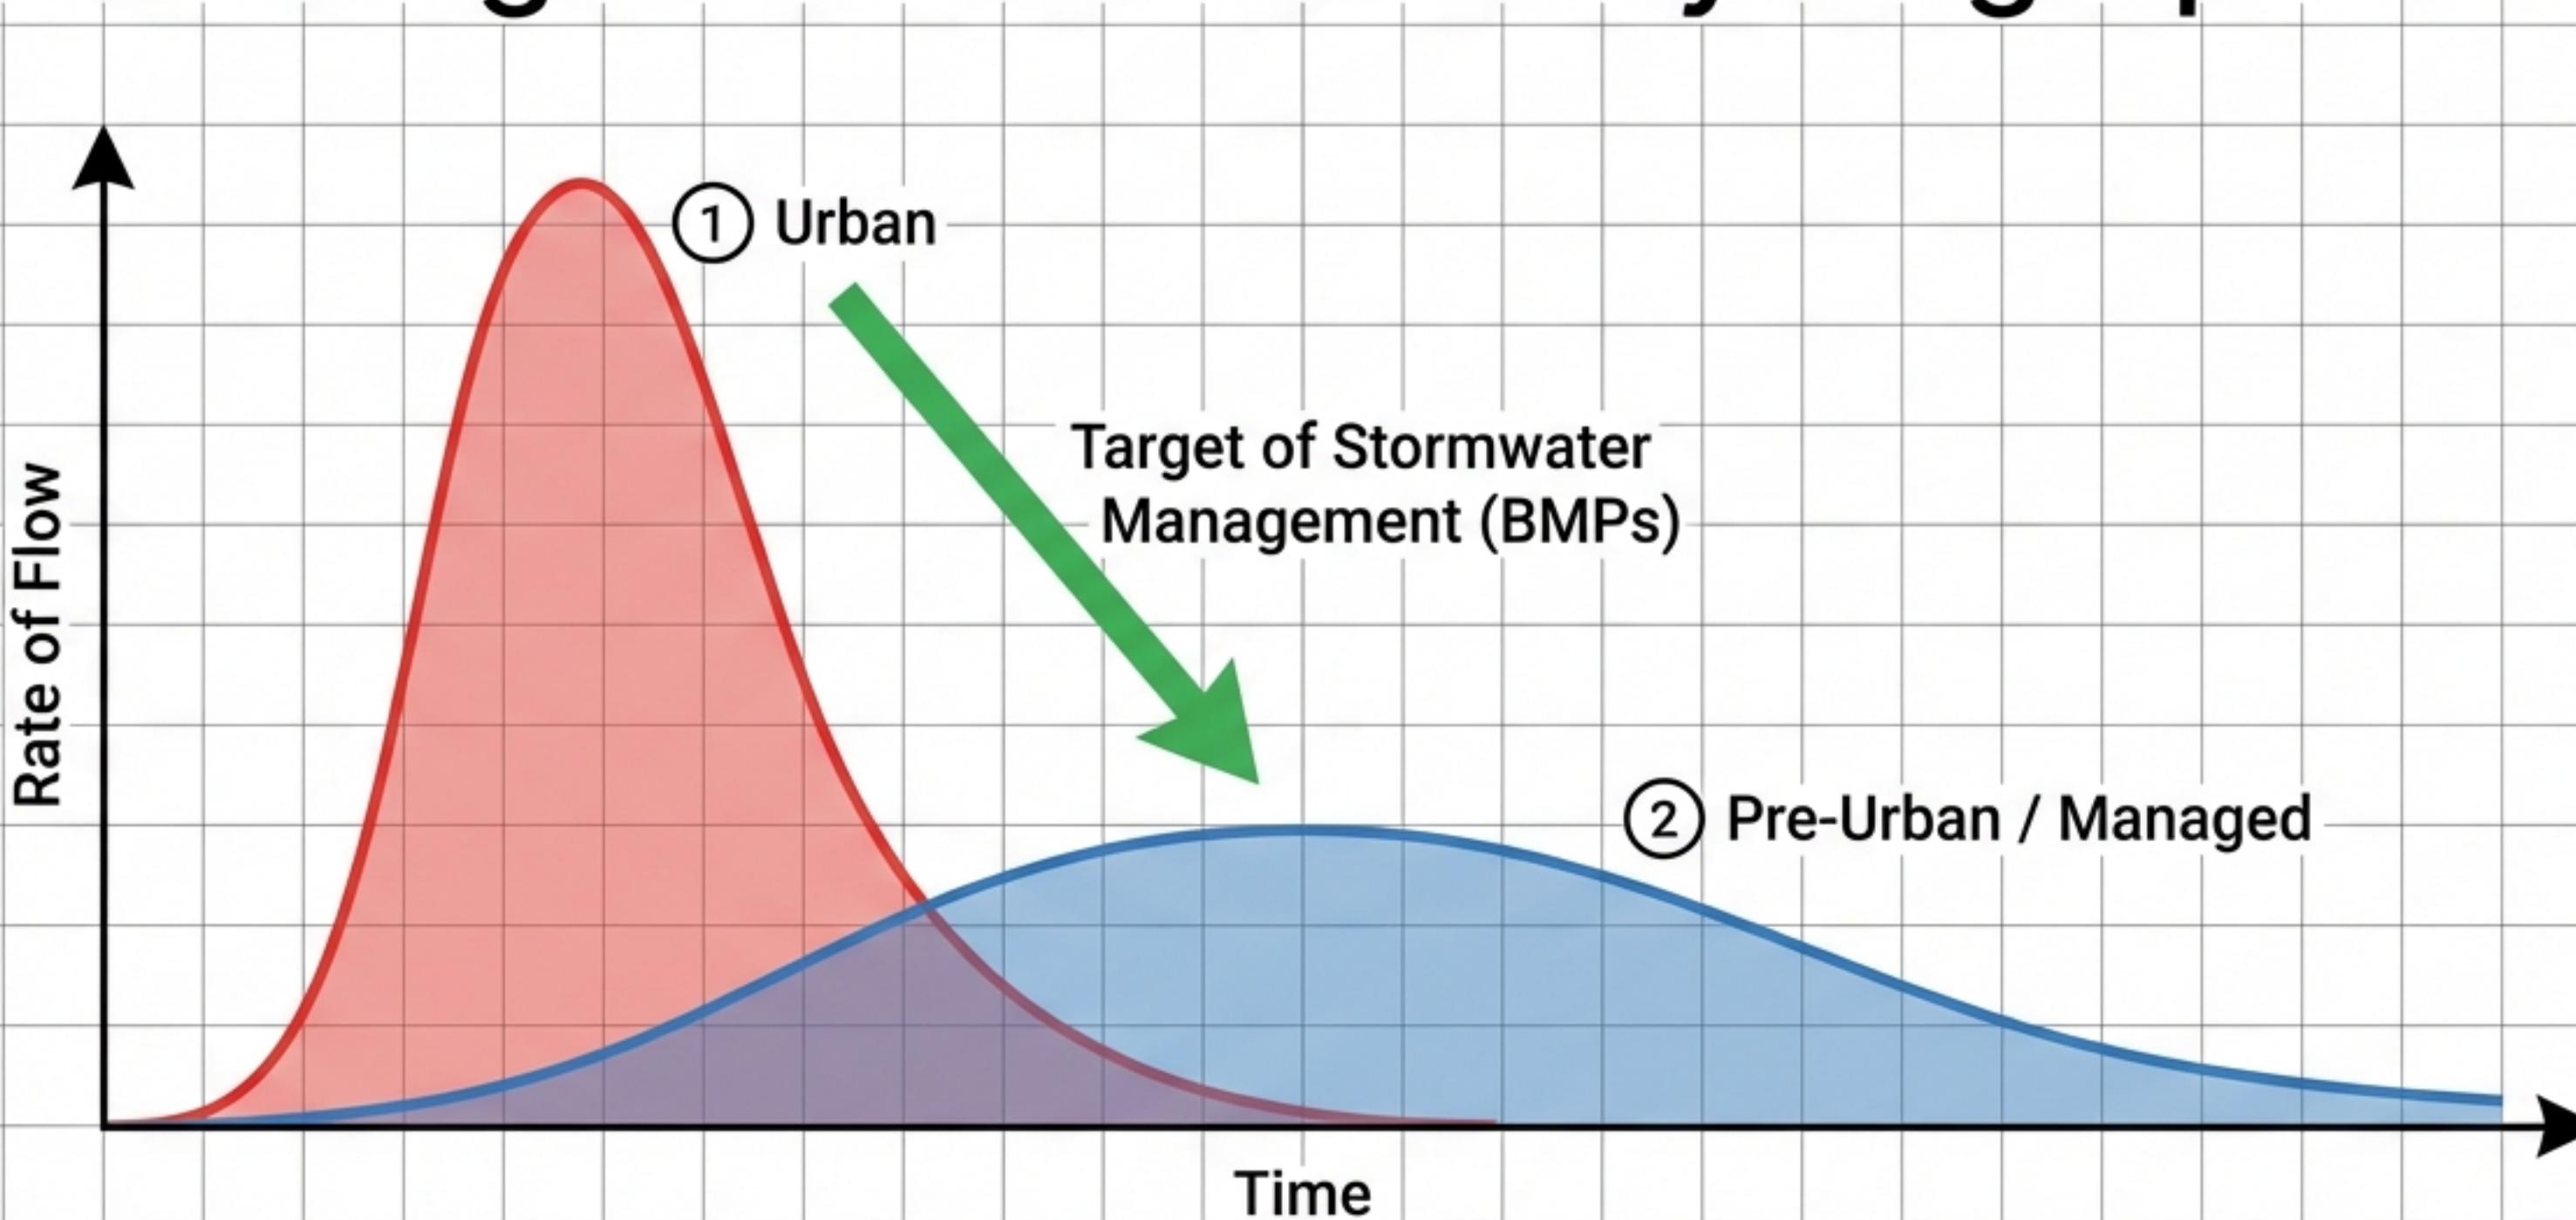

## Step 3: Calculate Effective Runoff (Pe)

$$P_e = \frac{(6.36 - 0.2(6.21))^2}{6.36 + 0.8(6.21)} = \mathbf{2.31 \text{ inches}}$$

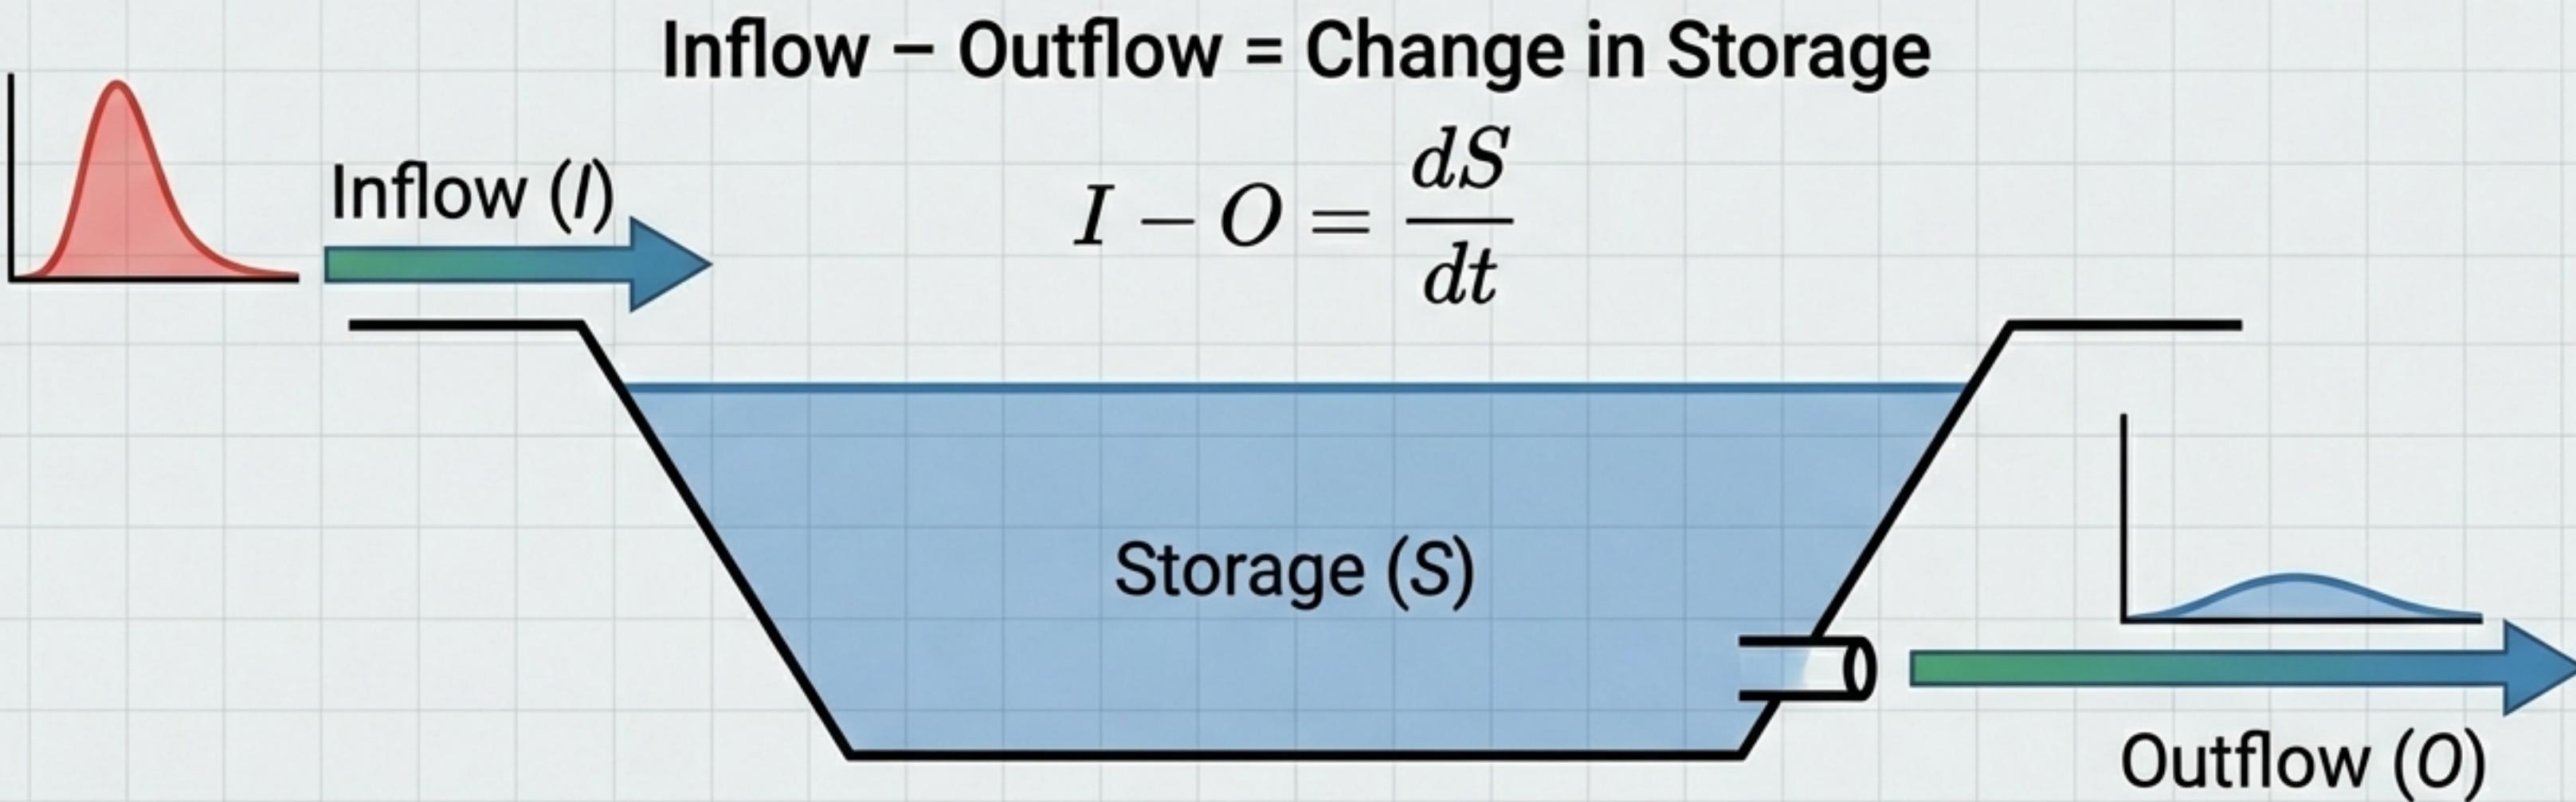

Result: Out of 6.36 inches of rain, the soil absorbs ~4 inches. The infrastructure must handle the remaining 2.31 inches of runoff.

# Visualizing the Storm: The Hydrograph

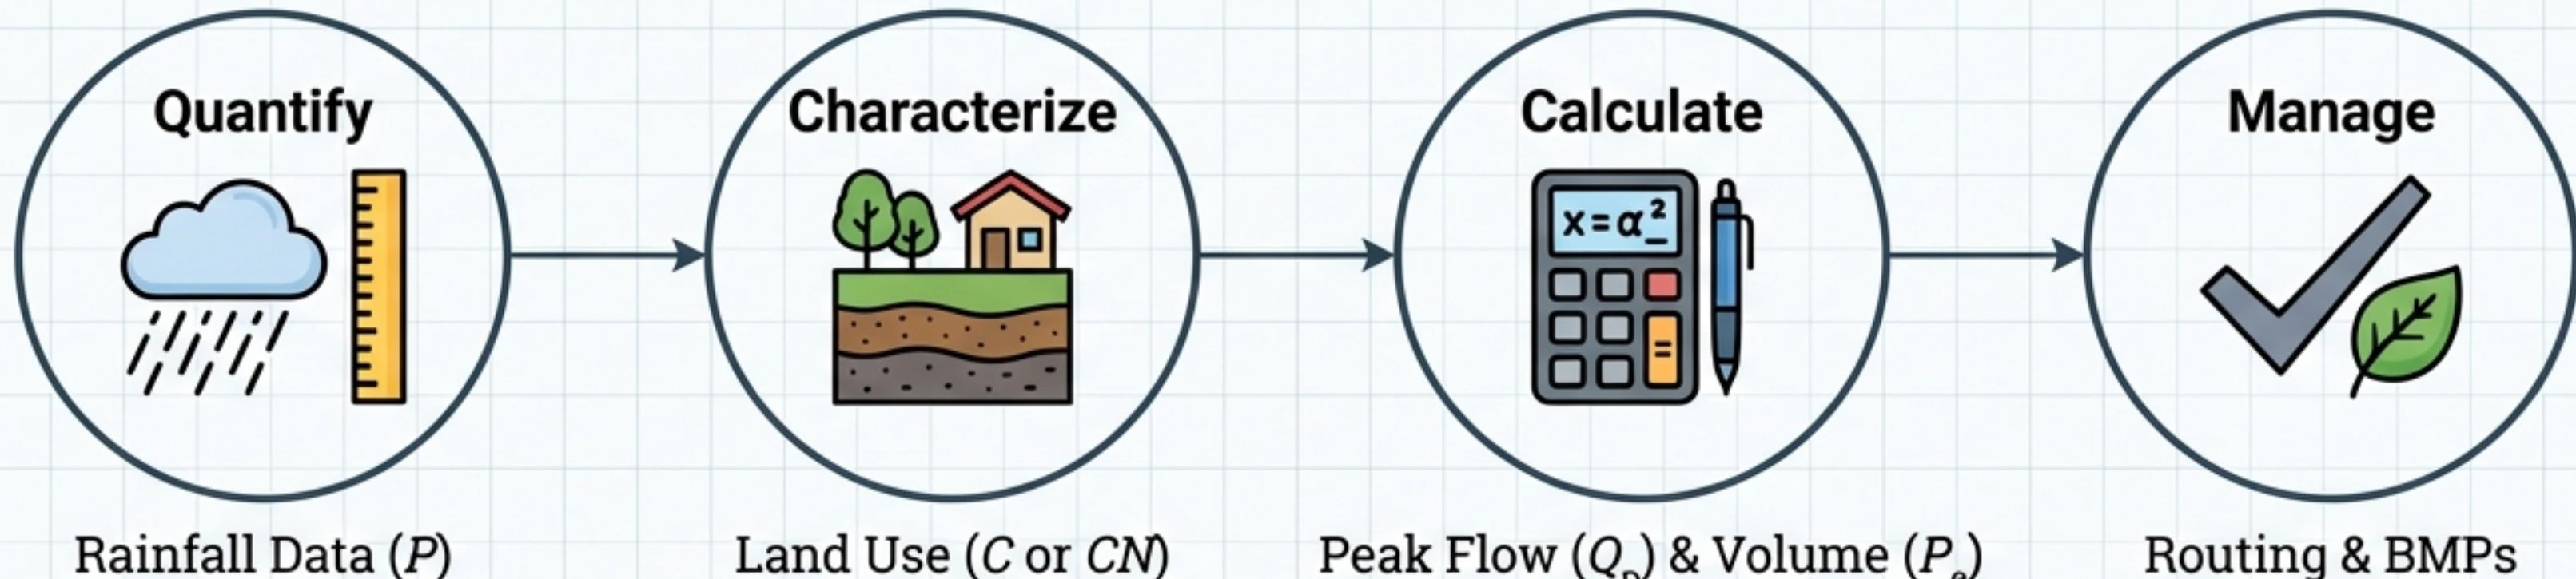

# Hydrologic Routing: Managing the Flow

We use detention basins to flatten the hydrograph. This process is modeled using the “Level Pool Routing” method.

# Summary: The Hydrologic Design Cycle

Effective stormwater design is not just about moving water away—it's about restoring the natural balance to protect our communities and environment.
